Selecting Top Bureaucrats: Admission Exams and Performance in Brazil*

Ricardo Dahis † Laura Schiavon ‡ Thiago Scot §

April 2020

Abstract

In the absence of strong incentive schemes, public service delivery crucially depends on bureaucrat selection. Despite being widely adopted by governments to screen candidates, it is unclear whether civil service examinations can predict job performance. This paper investigates this question by focusing on a highly prestigious and influential set of bureaucrats in Brazil: state judges. We first explore data on judges' monthly output and cross-court movement to separately identify what share of observed performance is explained by judges and courts. We estimate that judges account for at least 23% of the observed variation in the number of cases disposed. Using a novel data set on examinations, we then show that, within cohorts of candidates taking the same exam, those with higher grades perform better than their lower-ranked peers. Our results suggest that competitive examinations can be an effective way to screen candidates, even among highly qualified contenders.

1 Introduction

Public employees play a key role in designing and delivering essential public services to development worldwide (Finan et al., 2015). Recent studies have focused on the role that incentives and monitoring can play to improve the performance of government employees, particularly of frontline providers. However, the impact of such tools is limited for the typical bureaucrat in developing countries whose career is often characterized by tenure benefits, absence of performance pay, and promotion based on seniority (Bertrand et al., 2019). In the face of such low-powered incentives once hired, the issue of how to select bureaucrats becomes essential.

One widely used selection mechanism, particularly in some of the largest developing countries like Brazil, China and India, is competitive, impersonal examinations. These may reduce corruption and patronage in hiring by political leaders (Colonnelli et al., 2019; Brollo et al., 2017; Weaver, 2016), but potentially at the expense of assessing candidates' soft and noncognitive skills[1]. Further, it is an open empirical question, and a highly policy-relevant one, as to whether examinations reliably select candidates who are productive on the job .

In this paper we provide evidence from Brazil that objective examinations predict job performance for a highly selected group of public sector employees: state judges. Similar to the majority of civil servants in Brazil, judges are selected through highly competitive and mostly impersonal examinations, comprised of written and oral exams. Candidates are ranked based on their grades and top performers are offered jobs based on pre-specified number of available positions. Our estimates suggest that, within selected candidates, those ranking higher in exams are also high performers on the job as judges. In terms of magnitudes, we show that candidates that rank in the top quintile in their admission exam cohort dispose of approximately 20% more cases on a monthly basis than those in the bottom quintile.

The first step of our analysis is to estimate judge-level measures of performance. To do so, we use administrative data to construct a panel of judicial productivity at the judge-court-month level, covering the universe of state judges working in Brazil from 2009 through 2015. Across the 76 months encompassed by our data, judges often work in several different courts. This mobility allows us to estimate a two-way fixed-effects model akin to those in the labor literature decomposing wage variation between worker and firm fixed-effects. We separately estimate judge and court fixed-effects, and show that judges are important in explaining the observed variation in output: individuals' fixed effects account for at least 23% of the variation in the number of cases disposed.

We focus on the number of cases disposed for two reasons. First, timely delivery of judicial decisions is critical in developing countries. At the current pace of case disposition, it would take Brazilian courts three years to clear the backlog, assuming no additional cases were initiated (Conselho Nacional de Justiça, 2018). Ponticelli & Alencar (2016) show that ju-

[1]These characteristics of public sector recruitment differ markedly from what is observed in the private sector, where managers and human resources officers have wide discretion in selecting employees and subjective assessments plays an important role through interviews, for example (Hoffman et al., 2018).

dicial timeliness matters for important economic outcomes. They explore differences in court congestion across Brazilian municipalities to show that a bankruptcy reform has larger effects on investment and financial access of firms located in district with more efficient courts. Second, the speed with which judges dispose of cases is considered an important indicator of performance by Brazil's judicial branch and is used, along with other considerations, to define promotions throughout judges' career.

Yet, theory suggests that if the quantity of cases disposed is easily observable but quality is not, judges might divert efforts into the observable dimension of performance, possibly to the detriment of quality (Holmstrom & Milgrom, 1991). In other words, it is possible that what we deem to be high performing judges may actually be those diverting efforts away from quality dispositions in favor of more easily observable performance dimensions, namely speed. We try to ease concerns that our measure picks up high speed, low quality judges by observing one important input for court decision: the number of hearings held by judges. We re-estimate our two-way fixed-effects model using hearings as the dependent variable and show a strong, positive correlation between judges fixed-effects in both models. This suggests that faster judges are not decreasing the number of hearings, which we interpret as a proxy for inputs in the decision making process of case disposition.

Having obtained measures of individual job performance and showed that judges matter in explaining courts' output, we turn to the question of whether judges highly ranked on entrance exam actually perform better on the job. We collect novel data on admission exams for over 25% of all state judges working in Brazil during the period covered by our productivity dataset, including their final rankings and grades. Our results suggest a positive and strong correlation between admission exam and on-the-job performances: we estimate that, within cohorts, being ranked in the top quintile of one's admission examination is correlated with a 0.2 s.d. increase in estimated FE when compared to the bottom quintile. This result is robust to different measures of performance both in exams and on the job; the results are also robust when excluding of the top and bottom candidates in each cohort.

Taken as a whole, our results suggest that admission exams are able to rank candidates in a way consistent with their future performance on the job[2]. In order to make progress in understanding which dimensions of the exams are most relevant for future performance, we restrict our sample to a subset of judges for which we can break-down final grades in each of the recruitment phases and consider whether achievement in any of the specific exams is particularly predictive of performance on the bench. Across different specifications, grades on the Judicial Decision Writing exam, where candidates are given a hypothetical case and asked

[2]The implications of sidelining any subjective assessments of candidates' qualities for job performance are not obvious. If knowledge about objective exam content is the crucial requirement to perform well, or if subjective traits that predict exam performance are also correlated with service delivery capacity, then objective recruitment strategies might be simultaneously effective and impartial. If certain subjective characteristics are very relevant to perform well on the job but hard to capture on objective admission examinations, nonetheless, these recruitment strategies are maintaining impartiality at the expense of accuracy.

to produce a decision, are the strongest predictors of performance. While these correlations should be interpreted with caution, they suggest that the use of impersonal examinations to screen candidates might be particularly efficient if focused on "practical" exams that mimic the situations faced by employees on the job.

Our paper contributes to the recent literature on the selection of workers in the public sector. The impersonal admission examinations used to select judges is aimed precisely at avoiding the kind of patronage documented in contexts as different as colonial governors in the British Empire (Xu, 2018) and public officials hired at the discretion of newly elected politicians in Brazil (Colonnelli et al., 2019). However, the use of discretion when selecting officials need not lead to negative selection of providers. In an extreme example, Weaver (2016) shows that the selection of community health workers' supervisors by outright bribery leads to high quality workers being hired, since wealth and performance are strongly positively correlated. Our paper provides evidence that performance in impersonal admission exams are predictive about the timely disposition of cases within the judicial system in Brazil.[3]

Our research also adds to efforts of measuring the role of bureaucrats in determining public sector performance (Finan et al., 2015). While the relevance of front-line service providers like teachers (Chetty et al., 2014; Muralidharan & Sundararaman, 2011) and community health workers (Deserranno, 2019; Ashraf et al., 2014; Weaver, 2016; Dal Bó et al., 2013) have been extensively discussed, the role of other decision-makers in the public sector bureaucracy has only recently garnered more attention. Our empirical strategy, exploring the movement of judges between courts to identify individual fixed-effects, is particularly related to the work of Best et al. (2017) on the role of procurement officers in Russia in explaining price dispersion in public purchases, and of Fenizia (2019) on how managers of Social Security offices in Italy explain variation in productivity.

We also contribute with new evidence about the determinants of judicial efficiency in the developing world. Research in Pakistan (Chemin, 2009), Senegal (Kondylis & Stein, 2018) and Mexico (Sadka et al., 2018) has shown that judicial reforms aimed at simplifying procedures and speeding up the disposition of cases can be effective. Kondylis & Stein (2018), in particular, collect rich data at the case-level and show that higher speed in commercial courts in Senegal does not seem to affect the quality of decisions. The effects of judicial reforms more broadly also depend on the capacity of courts to deliver timely decisions, as shown in Ponticelli & Alencar (2016). Our paper adds to the literature by first documenting that judges are an important determinant of court efficiency, and then by showing that the screening process successfully selects the most efficient magistrates.

The remainder of this paper is organized as follows. Section 2 describes the structure of Brazilian courts and the admission process for judges. Section 3 presents the data used,

[3] Aman-Rana (2020) documents that public officials ranked at the top 10% of their admission cohorts in Punjab, Pakistan, also collect more taxes. Bertrand et al. (2019) documents a positive correlation between admission exam rankings and performance measured by 360 degree evaluations of IAS officers in India.

provides descriptive statistics and explains how we obtain the sample used when estimating the two-way fixed-effects model. Section 4 describes our empirical model, identification and estimation procedures. The main results are presented in Section 5, while Section 6 concludes and discusses some avenues for future research.

2 Institutional Context

2.1 Brazilian Courts

The Brazilian Judiciary is comprised of five branches: State, Federal, Electoral, Labor and Military Courts. This paper uses data exclusively from State courts, which cover all cases that are not specifically under the competency of the other branches (that is, State courts have residual judicial competency). The majority of criminal and civil cases fall under the competence of State courts: in 2017, over 60% of all cases in the Judiciary were allocated to the first instance of these courts (Conselho Nacional de Justiça, 2018).

Each of the 27 Brazilian federative units (26 states plus the federal district) is responsible for establishing and organizing the state courts. Within each state, the main administrative unit of the state justice are the judicial districts (*comarcas*), which encompass one or more municipalities. Judicial districts are mainly divided in three administrative levels, related to the underlying demand for judicial services: *first level* districts are located in rural or less urbanized municipalities and contain a single court of general competency (i.e. it covers all types of cases); *second level* districts are located in municipalities with smaller cities and encompass specialized courts, often separate Civil and Criminal courts; while *third level* districts encompass the state capital and possibly other large cities, and include several specialized courts.

Court congestion is considered a serious impediment to the efficient application of justice in Brazil (Ponticelli & Alencar, 2016): at the state level, there were over 60 million cases allocated to courts in 2017. If no more cases entered the justice system and current levels of productivity were held constant, it would take almost three years to clear the backlog (Conselho Nacional de Justiça, 2018). While overall congestion is very high, there exists a large dispersion among judicial districts not fully explained by simple regional differences: Schiavon (2017) shows that the dispersion of several congestion and performance measures is larger within states than between states, highlighting the relevance of local determinants in explaining variation in performance.

The importance of timely decisions by courts and the challenges faced by the Brazilian Judiciary in that regard have not escaped the attention of policy-makers and legislators. For example, the 2004 Constitutional Amendment that created the National Justice Council, among several other sweeping changes to the organization of the Judiciary, also included specific language requiring that judges' promotion take into account "objective criteria of productivity"[4].

[4]Constitutional Amendment n.45, December 30th 2004.

During the launch of the Open Justice System, in 2008, a Supreme Court Justice praised the tool as a way to "improve the management of justice and decrease the slowness of decisions"[5].

2.2 Selection of judges through competitive examinations

The broad rules for judges' recruitment are determined by Article 93 of the Brazilian Constitution. It states that all judges should be selected through public examinations (*Concursos Públicos*); since 2004, a Constitutional Amendment also institutes the requirement of three years of professional judicial experience. Judgeship admission exams are highly competitive (the ratio of candidates per position often exceeds 100), not only due to the prestige of the position but also likely because it is among the highest paid in the public sector[6]. Until 2009, federal law did not detail the content or structure of these examinations, which were left to the discretion of State courts. Since then, the structure of exams, including minimum content, qualification thresholds in each phase and weights for final ranking were harmonized[7].

In practice, nonetheless, the overall structure of these examinations was already rather similar across states. Upon deciding to hire new judges, courts publicly announce the beginning of a *Concurso* through a call for applications, informing how many positions are available and details about the timeline, content and structure of examinations. Potential candidates must enroll online and pay a fee[8] in order to be considered eligible for the position.

Most examinations are comprised of four phases: Multiple Choice, Written, Judicial Decision Writing and Oral Exams. The first phase is often a *Multiple Choice Exam* covering a wide range of topics: constitutional, civil, criminal, commercial, administrative and family law are among the themes covered. Like the other three phases, this exam is both qualifying, meaning that candidates with performance below a certain threshold are immediately eliminated, and classifying, since the grade received is a component of the weighted average that determines the final ranking of candidates. Those approved in the Multiple Choice phase are invited to take a *Written Examination* that encompass the same topics mentioned before and also topics such as the sociology and philosophy of law, and ethics. The following phase is a *Judicial Decision Writing*, also called a "practical exam", where candidates are given a hypothetical case and asked to write a judicial decision. In most cases this phase includes two decisions, one in criminal and another in civil law. The last qualifying phase is the *Oral Exam*. Candidates are randomly assigned a topic from a pre-determined list 24 hours before their examination, and are then expected to answer questions from a committee composed of other judges and

[5]https://www.estadao.com.br/noticias/geral,para-stf-criticas-ao-justica-aberta-sao-infundadas,195051

[6]While the Constitution establishes that wages in the public sector should not surpass those of Supreme Court Justices, set at R$ 33,763 (approximately USD 8,500) per month until 2018, the vast majority of judges receive total compensation significantly higher than that due to fringe benefits not included in the above mentioned rule.

[7]National Justice Council Resolution 75 05/12/2009

[8]Resolution 75 determines that the fee can be no greater than 1% of the gross monthly salary for the position, which amounts to around R$ 300 or USD 75.

attorneys.

Candidates approved in the *Oral Exam* are eligible to be in the final ranking that defines hiring. Other than the grades in each of the previous phases, the final score also includes the so called *Titles Exam* (*Exame de Títulos*), additional points for career and academic achievements, such as previous judgeship, professorship or advanced degree in Law, and publications in Law journals. Since 2009, the weights that define the final score are the following: 10% Multiple Choice, 30% Written Exam, 30% Judicial Decision Writing, 20% Oral Exam and 10% Title Exam. Candidates are ranked according to their final grades and the top performers are offered jobs according to the number of vacancies available.

It is worth briefly mentioning that these recruitment processes are considered transparent and free from undue influence of judges or politicians, unlike the hiring for other public sector positions which are heavily influenced by patronage practices (Colonnelli et al., 2019; Brollo et al., 2017; Barbosa & Ferreira, 2019). First, every step of the process is highly publicized: grades and lists of approved candidates in each phase are made public, as are the content of each exam. The composition of the committee writing exams and participating in the Oral tests is also made public at the beginning of the *Concurso*, and candidates can appeal for the exclusion of members (e.g. due to family ties of members to any candidate). Second, any deviation from the stipulated rules regarding exams often leads candidates to sue and annul specific phases or even the entire recruitment process. In 2014, for example, candidates in the state of Para successfully sued to have their Oral exams annulled after being asked only three questions during the evaluation, while the call for applications determined four questions[9]. In that sense, the selection process of judges is believed to be broadly free from corruption and reflect the performance of candidates[10].

2.3 Judges' careers and allocation of cases

Once hired, judges are considered "substitute judges" for a period of two years, a probational stage before gaining tenure protection. After this period judges can only be dismissed if convicted of crimes or found guilty of administrative infractions. In practice, this is very rare: between 2005 and 2017, only 82 judges in the entire Judicial branch were punished by the National Justice Council, and 53 of those received "mandatory retirement", meaning they were excluded from judgeship but kept receiving salaries[11].

As previously discussed, judicial districts are divide in three levels: first, second and third.

[9]http://cnj.jus.br/noticias/cnj/61524-cnj-anula-prova-oral-de-concurso-para-ingresso-na-magistratura-do-tjpa

[10]Exceptions do exist. In 2010 the Supreme Court ruled in favor of candidates asking for the annulment of a *Concurso* in the state of Minas Gerais, arguing that more candidates were accepted to the second phase of the process than initially announced. Two daughters of an appellate judge from that state were benefited (https://www1.folha.uol.com.br/fsp/poder/po2606201029.htm)

[11]https://g1.globo.com/politica/noticia/cnj-puniu-82-juizes-no-brasil-desde-2005-53-deles-continuam-recebendo-salario.ghtml

This administrative division is directly linked to judges' careers. Substitute judges are often allocated to first level districts, where they work in general courts, dealing with all types of judicial cases. Promotion means being reallocated to a higher level district, which comes with wage increases. After achieving third level status, judges can be promoted to appellate courts, meaning they leave the first instance (and our database).

The allocation of magistrates to judicial districts is governed by the Constitution. One of the core principles considered is that of the *immovability* of judges, meaning that judges cannot be transferred from their assigned district without their consent. The principle is supposed to protect the public against the undue influence of politicians who might want to exclude a judge from judging a case in which they have interest, for example, but it is also a clear benefit to judges who are only reassigned if they so decide. This should make clear that in no way we argue that the movement of judges between courts is quasi-random: judges must assent to being transferred between districts[12]. The identification of judges' fixed-effect, therefore, does not rely on exogenous allocation of judges to courts; our model allows for rich patterns of endogenous matching between judges and courts, and as discussed in detail below only rules out specific types of matches.

Finally, it is important to note that the distribution of cases among judges is as good as random. In judicial districts where there is only one court, cases will be randomly assigned to one judge in that court. For larger districts that encompass specialized courts, cases will be assigned to the proper court depending on their topics or, in the case where more than one relevant court exists, randomly assigned to one of the courts and a judge. That should allay concerns that, within courts, different judges will have distinct composition of cases, making it harder to interpret the number of cases disposed.

3 Data and descriptive statistics

3.1 Data sources

This paper uses three main data sources: information on monthly output of judges and courts provided by the Open Justice System, admission exam's rankings collected from several different sources and administrative data on formal employment (*RAIS*).

All data on judicial performance come from the Open Justice System (*Sistema Justiça Aberta*), an online platform maintained by the National Justice Council[13] (*Conselho Nacional de Justiça - CNJ*). The Open Justice System provides monthly information, supplied by courts,

[12]In our empirical exercises we explore the movement of judges between courts, which can occur in courts within a same district or between different districts. The immovability principle applies to the latter.

[13]The National Justice Council was created in 2004, through a Constitutional Amendment, with the goals of improving the efficiency and transparency of the Brazilian judiciary. Among other tasks, the Council receives complains from citizens against members of the judiciary, promotes tools to improve the efficient functioning of the courts and publishes data on judicial efficiency.

on a range of quantitative outcomes at both the court and judge levels, including the number of cases disposed, hearings and intermediary decisions.

We construct a panel at the month-judge-court level: each observation is a vector of quantitative outcomes related to a judge working on a given court in a specific month. The dataset covers the universe of state judges working on first instance courts (i.e. excluding appeal level) from January 2009 through April 2015[14], and we construct unique IDs using judges' full names to track the movement of magistrates between courts over time.

Our preferred measure of judges' performance is the number of *cases disposed on merits* in a given court and month. This refers to the number of cases for which the judge has issued a final decision based on the merits of the process, i.e., it excludes any cases terminated for procedural reasons or by a decision of one of the parts to withdraw. The decision to exclude cases decided for other reason rather than on the merits is an attempt to reduce the possible noise introduced by considering cases that are concluded for reasons unrelated to the judges' efforts.

Figure 1 presents preliminary evidence on the dispersion of judges' output. We plot the histogram of average monthly number of cases disposed at the judge level, across the entire panel. There is remarkable dispersion: judges on the 10th percentile of the distribution dispose of 11 cases on the merits on average, while judges on the 90th percentile dispose of 8 times as many. This dispersion reflects several forces, including potentially judges' efforts and capacity to make the court function efficiently, but also levels of demand in different courts. We will attempt to disentangle these determinants with our empirical model.

The data on entrance examinations (*Concursos*) was collected from a variety of sources. Results of *Concursos* are mandated to be public and are often published in PDF format either on the website of the State courts hiring or by the private institutions hired by the state to manage and implement the recruitment process. We scrapped these document and constructed a database of candidates' exam performance. We have collected data for 79 recruitment waves for the selection of Judges from 24 different states in the period 2000-2013. For all these examinations the final ranking of approved candidates is available; for a subset of them, we also collect the final grade and the individual grades in all phases of the exam[15]. We then match judges' grades with performance using full names and state of judgeship[16]. We are able to match over 2,800 judges observed in the productivity dataset to their admission examination performance, covering over 25% of all state judges working at some point between 2009 and 2015.

One additional data source used to recover information from judges' careers is adminis-

[14]The Open Justice System was extinguished in 2015, and replaced by a new system later that year. The new dataset, nonetheless, is not strictly comparable to the data we use.

[15]Recent recruitment processes always include results for all the phases of the examinations. As we go back in time, nonetheless, the information available online becomes scanter. The minimal information we require to include an examination in the dataset is the nominal list of approved candidates and their final rankings.

[16]We benefit from the fact that Brazilians often hold several last names, which makes precise matches on names feasible.

trative matched employer-employee data from *RAIS* (*Relação Anual de Informações Sociais*) for the period 1995 - 2017. We use unique individual identification numbers (*CPF - Cadastro de Pessoa Física*) to follow individuals over the years, and then match workers at RAIS to the judge productivity database using full names. We are able to uniquely match approximately 9,400 judges between the two datasets, or 80% of all judges observed in the productivity dataset in the period 2009-2015. We use RAIS data to obtain information on judges' gender, education, formal labor market experience, experience as judges and wages (prior to and during judgeship).

3.2 Sample Selection and Descriptive Statistics

The complete productivity dataset comprises close to 1,000,000 observations at the judge-court-month level. Here we briefly describe the steps to obtain the sample used to estimate the two-way fixed effects model.

Despite the efforts by CNJ to assure quality of the performance data reported, there are clear instances of incorrect entries, such as hundreds of thousands of cases disposed by a single judge in a month. We therefore trim all performance measures at the 99th percentile[17]. We also observe a very high frequency of "mobility" in the raw data, as presented in column (1) of Table 1: on average judges work in 11 different courts throughout the period. Yet, a large proportion of these judge-court matches is clearly transitory: for over half of the judge-court pairs the duration of the match is a single month[18]. In our estimates, we drop any judge-court *spells* with a duration of less than three months. Our final sample includes approximately 730,000 observations.

Table 1, column (1) presents descriptive statistics for the full panel, while column (2) refers to the sample used to estimate the two-way fixed-effects model[19]. There are 10,479 different judges and 9,048 courts in the estimating sample. Unlike other settings where there is limited mobility explored to estimate two-way fixed-effects models, that is clearly not a problem in our context: almost 80% of judges work in at least two different court throughout the period, and only in about 10% of courts we observe a single judge in the entire period.

The first panel of Table 1 characterizes judges in the sample. While the panel covers a 76-month period, the median judge is observed working on any court in 56 months. Very few judges work in one single court throughout these five years: on average judges work in four different courts. While judges might work in more than one court on a given month, that is the exception rather than the rule: for over half of judge-month observations, magistrates are working in a single court. Once we drop short-lived judge-court matches, the average number of months for any match is over 16 months and the median 9 months, meaning that

[17]For case disposition, the 99th percentile is 350 cases disposed by a judge in a single month.

[18]Informal conversations with judges suggest that it is common for judges work in different courts when colleagues are on vacation or sick leave.

[19]Table A1 in the appendix presents detailed descriptive statistics for the estimating sample.

we have several repeated observations of output for each pair, reducing the noise inherent in a measure like the number of cases disposed.

Details about courts are presented in panel B of Table 1. While in any given month most courts are likely to be staffed by a single judge, their rotation means that, throughout the period, the average number of different judges working in a court is almost five, or one per year. We also present the breakdown of courts by category, according to the type of cases they hear. General courts, located in first level districts and handling all types of cases, comprise around 20% of the sample. The remaining courts are specialized on specific cases, such as Civil (22%), Criminal (16%), Small-stakes (18%) and Family Law (10%). As one might expect, courts dealing with different topics present systematic differences in the number of cases disposed on a monthly basis. Figure 2 presents the average monthly number of cases disposed by judges, in each type of court. On one extreme, judges in criminal courts typically dispose of only 20 cases per month, while judges in small-stakes courts, which deal exclusively with less severe criminal cases or low-value civil cases, dispose of almost 50 cases. This highlights why simple comparisons of performance between judges working in different courts might be misleading, and the need to condition on court fixed-effects when estimating judge-level performance.

Descriptive statistics on judicial performance are presented in panel C of Table 1. The average number of case disposed on the merit per month is 40, but the distribution has a long right tail (maximum number is 350) and a non-negligible number of zeros: in 13% of judge-court-month observations the number of cases disposed was zero. As discussed below, this motivates our main specification using the inverse hyperbolic sine of cases disposed as the main explanatory variable. The Table also shows that the average number of hearings is 35 (median = 17).

The assessment of the predictive power of admission exams about judge performance relies on a smaller subsample of individuals matched between the two datasets. We present descriptive statistics for that matched sample in column (3) of Table 1. We are able to match 2,881 judges in the productivity sample to their admission exam ranking, or 28% of judges observed in the estimation sample. Judges in the matched sample are observed for less months (45 vs. 50 months in non-matched sample), work in more courts (5.9 vs. 4.3) and have slightly lower monthly output of cases disposed on the merit (36 vs. 40). It is important to note that candidates in the matched sample are not a random sample of the universe of judges. In particular, Figure 3 highlights the share of judges we are able to match to recruitment exams by state: whereas in some states like Minas Gerais (MG), Paraná (PR) and Acre (AC) we obtain grades for almost half of judges, three states are not represented at all (Amapá (AP), Rio Grande do Norte (RN) and Rondonia (RO)).

4 Empirical strategy and identification

4.1 Empirical Model

In order to estimate the permanent component of performance for judges, our main challenge is to separate the individual contribution of judges from the effects of courts they work in: courts in larger district might have inherently more demand, or even within districts there might be systematic differences in length of cases between courts, so we cannot simply compare the performance of judges working in different courts. In order to do that, we borrow from the labor literature and estimate a two-way fixed effects model.

We model the number of cases disposed as follows. For a given judge j working on court c on month-year m, we model (the inverse hyperbolic sine of) the number of cases disposed as:

$$y_{jcm} = \theta_j + \gamma_c + \alpha_s + \boldsymbol{X}'_{\boldsymbol{jcm}}\boldsymbol{\beta} + \epsilon_{jcm} \tag{1}$$

where θ_j refers to the permanent component of judge effect; γ_c refers to permanent component of court effect; and X_{jcm} is a vector of time-varying controls. In our baseline specification X_{jcm} includes month-year indicators, the number of courts a Judge work in on a single month and the number of judges working in each single court[20]. Note that we also include an intercept for each connected set, α_s. As previously mentioned, the number of cases disposed is zero in approximately 13% of observations in our dataset. To deal with this, we use the inverse hyperbolic sine transformation (Bellemare & Wichman, 2018) of the number of cases disposed, which, unlike the log transformation, does not drop observations with zero cases disposed.

The separate identification of judge and court fixed-effects in the model above, as shown by Abowd et al. (2002) in the context of workers and firms, is only possible within connected sets - groups of individuals and organizations connected by movers, individuals who work on different organizations throughout the period. Formally, within each connected set g with C_g organizations and J_g individuals, we can identify at most $C_g + J_g - 2$ effects.

The vast majority of judges work in several courts during the period, and even in more than one court in the same month, meaning that connected sets *within states* are very large: in the majority of states the largest connected set comprises over 95% of judge-court-month observations, and only one state it comprises less than 90%[21]. Within each state, we lose very few observations by restricting our sample to the largest connected sets.

[20] Both the number of judges working in a court and the number of courts a judge works on are computed in the full sample, and not in the estimating sample. While we do not use the variation coming from short judge-court matches, our estimates take into account that, for any given month, judges might be "moonlighting" in other courts and thus have lower performance.

[21] In the small state of Sergipe (SE), the largest connected set comprises only 65% of observations. Details about the largest connected set in each State and figures illustrating the construction of connected sets are presented in Appendix B.

As previously discussed in Section 2, however, judges are selected to work in a specific state, and never work in courts of different states. That means each state is a separate connected set, and we cannot compare court or judge fixed effects across states. While that is not an impediment to our analysis of the predictive power of entrance exams, since we only compare individuals in the same exam cohort (and therefore same connected set), adjustments are needed in order to perform the variance decomposition exercise.

We follow Best et al. (2017) in estimating the variance components with several connected sets. When estimating equation (1), we impose the additional restrictions that both court and judge fixed-effects have mean zero in each connected set. If we define $\tilde{\theta}_j$ and $\tilde{\gamma}_c$ to be the true judge and court fixed-effects, respectively, what we can identify in equation (1) are $\theta_j = \tilde{\theta}_j - \overline{\theta}_g$ and $\gamma_c = \tilde{\gamma}_c - \overline{\gamma}_g$, the deviations of the true effects from the connected set means. We can then write the variance of number of cases disposed as:

$$\begin{aligned} Var(y_{jcm}) =& Var(\theta_j) + Var(\gamma_c) + 2Cov(\theta_j, \gamma_c) + Var(\alpha_s) + Var(\boldsymbol{X}'_{jcm}\boldsymbol{\beta}) + \\ & 2Cov(\alpha_s, \boldsymbol{X}'_{jcm}\boldsymbol{\beta}) + 2Cov(\theta_j + \gamma_c, \alpha_s + \boldsymbol{X}'_{jcm}\boldsymbol{\beta}) + Var(\epsilon_{jcm}) \end{aligned} \tag{2}$$

Best et al. (2017) show that, since we can only estimate within connected sets variances, the estimates recovered are lower bounds of the total variance of both judges and courts fixed-effects. The total variance attributable jointly to judges and courts, nonetheless, can be recovered using the variance of the connected sets effects: $Var(\tilde{\theta}_j + \tilde{\gamma}_c) = Var(\theta_j + \gamma_c) + Var(\alpha_s)$.

4.2 Identification and estimation

As discussed in detail in Card et al. (2013), Card et al. (2016) and Card et al. (2017), identification in the two-way fixed-effects model does not require random allocation of workers (judges) across firms (courts). The structure of the model allows for rich patterns of sorting, including for judges that dispose of more cases to select into better courts, or for judges to specialize in certain courts where their output is higher.

Here we focus on assessing whether two particular issues affect the identification of our model. First, we model judge and court fixed-effects as additive and linearly separable. If that is not the case and there exists a judge-court match effect (i.e. more productive judges are particularly efficient in productive courts), then our estimates of judge effect might be biased. Figure 5 presents a heatmap where we break down residuals of our model by vingtiles of judge and court fixed effects, and graph the average residuals in each cell. To interpret these results, consider Figure 6, where we simulate a model in which there exists judge-court match effects, but we erroneously estimate a linearly separable mode. The residuals then are systematically large/small in cells with extreme fixed-effects, reflecting the incapacity of the model to capture the matching effect. Going back to Figure 5, the actual heatmap, we do not observe the same

pronounced pattern as in the simulation, suggesting that even if match effects are real (our model seems to be unable to match the outcomes at the very top cell in terms of both judge and court fixed-effects), they are not large enough to severely affect our estimates.

The second issue we consider is whether judges are moving into courts systematically due to *trends in court productivity*. While the selection of judges into courts due to levels of productivity does not affect our estimates, the same is not true if judges can select into courts because they are improving/decreasing their performance. To consider whether that seems to be the case, we perform an event study that assess how the number of cases disposed by judges evolve around the time judges transition between judicial districts[22]. Figure 8 reports the coefficients of the event-study, in which we consider the indicator for 6 months before the transition as the omitted category. Three things stand out from these results. First, productivity start falling in the last two months before a judge moves: knowing they will change courts, they might transfer their cases to other magistrates or put in less effort to dispose of more cases. Second, the fall in performance persists for at least three to fourth months after the transition, but six months after there is no distinguishable effect on performance. Finally, and most important for the model, there seems to be no selection in trends: judges do not seem to be on a trend to be more or less productive, either before or after the movement between judicial districts. These results suggest that selection on trends do not seem to be a threat to identification in this context.

Consistent estimation of individual fixed-effects require not only that the number of observations in a panel is large enough, but also that the number of periods in the panel grows to infinity. Since our dataset encompass around 70 months, finite sample bias will lead to excess dispersion in our estimates of both judge and court fixed-effects, inflating the estimated share of total variance explained (Best et al., 2017; Silver, 2019). We deal with that issue by using a non-parametric, split-sample correction method that shrink our variance estimates (Finkelstein et al., 2016).

We randomly split our sample in two, stratifying at the judge-court level, so that we preserve the number of judge-court pairs in both samples. We then proceed to estimate the two-way fixed effect model separately in each sample and obtain separate judge and court fixed-effect estimates. While FEs are noisily estimated in each sample, the errors should be uncorrelated due to the random split. Formally, if in each sample $s = \{1, 2\}$ the estimated judge fixed effect can be written as $\hat{\theta}_{(j,s)} = \theta_j + e_{j,s}$, where θ_j is the true FE for individual j and $e_{j,s}$ the error term, with $Cov(e_{(j,1)}, e_{(j,2)}) = 0$, then it holds that $Cov(\hat{\theta}_{(j,1)}, \hat{\theta}_{(j,2)}) = Cov(\theta_j, \theta_j) = Var(\theta_j)$. That is, we can recover the true variance of FEs by separately estimating variances in the random samples and calculating their covariance.

[22]It is much harder to create such event-study when judges start working in different courts in the same district, because they often do not clear leave one court for another, but keep "connection" to their old appointment. For that reason we restrict our analysis to clear changes of court when judges move from one district to another.

5 Results

5.1 Judges role in explaining variation in output

Before presenting the results decomposing the variance of total output, we present preliminary evidence that judge fixed-effects matter in explaining courts' output. Table 2, Columns (1) and (2), present goodness-of-fit measures when estimating Equation (1) excluding and including judge fixed-effects, respectively. The inclusion of judge fixed-effects increases the adjusted R-squared of the model by 8 p.p. and reduces the residual standard error (RSE) from 1.43 to 1.34. This is evidence that judges matter in explaining the variation in output observed across courts.

We present the results of formal variance decomposition in Table 3[23]. Column (1) presents the raw variance estimates, with no finite-sample corrections, while Column (2) present corrected variance estimates using split-sample strategy, and column (3) presents the share of total variance explained by each component using the split-sample estimates. The finite-sample corrected variance of judges' FE is very similar to the raw estimates, on the range of 0.74-0.80, suggesting that judges explain at least 23% of the total variance of output. To put that magnitude in context, it is significantly larger than the estimate of Fenizia (2019) on the share of social security offices' productivity in Italy explained by managers (9%), but very similar to those of Best et al. (2017) on the share of public procurement prices explained by procurement officers in Russia. The estimates for share of total variance explained by courts fixed effects, on the other hand, is more sensitive to the correction method, varying from 34 - 48%. Estimates for the variance explained by the sum of judge and court FEs range from 35 - 51%: since the sum of explained variance independently explained by judge and courts is much larger than that, it means the covariance of these fixed effects is large and negative, meaning that judges with higher FE are observed matched with courts of low FE, and vice-versa.

While the previous estimates show that judges are important in explaining the quantity of cases disposed and provided individual measures of judge performance, one might worry that judges that dispose of more cases are prioritizing quantity over quality. If that is the case, judges with higher fixed-effects in our model might actually be those that cut back on the inputs necessary to arrive at "good decisions", hastening the process to increase their case disposition number. We test whether this is a plausible explanation in our context by investigating one important input for case decision: the number of hearings that judges hold each month. To assess if "high fixed-effect" judges are conducting systematically less hearings than their peers with lower fixed-effects, we follow Silver (2019) and re-estimate the two-way fixed-effects model using the number of hearings as dependent variable, thus obtaining a new fixed-effect estimate for each judge. If judges are severely cutting back on hearings in order to increase their case disposition, we might expect a weak or even negative correlation between

[23]Due to the high dimensionality of fixed-effects, we cannot simply invert matrices to obtain OLS estimates. We then estimate the parameters using the *-lfe-* command in R, also used by Best et al. (2017).

the fixed-effects in both models. Figure 7 shows that this is not the case: fixed-effects from the two models are strongly positive correlated, suggesting that judges who dispose of more cases are also those that hold more hearings. While we are not able to assess whether the use of other inputs, including length or quality of hearings, this alleviates concerns that judges who dispose of more cases are systematically sacrificing on quality.

5.2 Correlates of judges' and courts' fixed-effects

In this Section we briefly describe whether estimated courts' and judges' fixed-effects are systematically correlated with observable characteristics. We start by presenting results for courts' FEs in Table 4. The first panel shows that courts' have higher fixed effects when located in judicial districts outside the state capital, with larger populations and higher urbanization rates. Conditional on time and judges' fixed-effects, this suggests that the number of cases disposed is particularly high in poorer, large urban districts outside the largest urban center of states. There are several possible explanations for that finding. If relative demand for judicial services is higher in these poorer areas, relative to supply, courts in those areas might present higher case disposition, possibly in detriment of decision quality. It is also possible that the composition of cases in these areas are different, and the higher number of cases in poorer areas reflect the fact that cases are easier to dispose. All those factors might co-exist, and will be picked up by courts' fixed-effects in our model. The results in Table 4 also shed light on how fixed-effects differ by the nature of cases assigned to each court. Similarly to what we observed in the simple descriptive statistics of Figure 2, criminal courts and those dealing with other topics such as commercial law (pooled with "others" here) have particular low level of case disposition when compared to general courts.

We now turn to describe how judges' fixed-effects correlate with observable characteristics. Here we rely on the sample matched to RAIS, the employer-employee database of formal workers, in order to construct judges' work history and obtain individual traits such as gender and age. Results are presented in Table 5. In column (1) we present results for all judges that are matched to RAIS, and in column (2) we restrict to judges that are observed at least once working outside of the judiciary, in order to include wages prior to judgeship as a correlate. All estimates include connected-sets (State) fixed-effects. Results in column (1) suggest that individual traits explain very little of the estimated effects: gender, education and experience, both in general and in the judiciary, are not significant predictors of judge fixed-effects. Age is correlated with the estimated effect, with a positive and concave relationship: older judges dispose of more cases, but the effect is diminishing in age. These results, however, are not very robust: when we restrict the sample to those observed working outside the judiciary since 1995, we no longer observe age as a significant predictor, but overall experience does seem positively correlated with case disposition. The coefficient on (log) average yearly wage received before joining the judiciary, which we interpret as potential earnings outside

of judgeship, is small in magnitude and not statistically different from zero.

5.3 Entrance exams are predictive of performance

Results in the previous sections are strong evidence that the identity of judges matters for the timely delivery of justice. While we are unable to explain the reasons why some judges are more effective in disposing of cases than others, the fact that we observe such differences in judge output suggests that the screening of judges might be one tool in improving judicial efficiency. We now turn to the question of how candidates performance in the admission exams is related to their performance on the job. In all the exercises that follow we use the sample for which we can match judges' admission exam performance.

We start by presenting "reduced-form" evidence that entrance exam ranks are correlated with the number of cases disposed on merits, once we control for court and month fixed-effects. That is, in here we do not use estimated judges fixed-effects, but simply present OLS regressions of the form

$$y_{jcm} = \boldsymbol{\beta' ExamRankQuintile_j} + \gamma_c + \delta_{w(j)} + \boldsymbol{X'_{jcm}\theta} + \epsilon_{jcm} \tag{3}$$

where y_{jcm} is the IHS transformation of cases disposed, $\mathtt{ExamRankQuintile}_j$ are indicators for quintile of exam performance of judge j in their exam cohort and δ_w are indicators for each cohort of candidates, since we can only meaningfully compare ranking among candidates sitting the same examination. Standard-errors are clustered at the judge-level.

Results are presented in Table 6, where the omitted category for exam quintile is the bottom 20%. Column (1) presents estimates for a regression that only includes cohort fixed-effects, while in Columns (2) and (3) we add Court and Month fixed-effects, respectively. Focusing on Column (3), the results suggest that, when compared to judges ranking in the bottom quintile of their cohorts, those in the top 20% dispose of approximately 21% more cases. The estimated effect is smaller but statistically significant and economically meaningful for judges with ranks in the second to fourth quintiles, and we can reject that the coefficient for the top 20% is identical to those on the second and third quintiles. In Column (4) we present a much more stringent exercise: we include court-by-month fixed effects, meaning that the only variation used comes from different judges working in the same court on the same month (hence the large drop in sample size, since observations for courts with a single judge in any given month are dropped). The estimated coefficients are slightly larger in absolute value, but broadly consistent with previous estimates suggesting that better ranking in entrance exams are correlated with higher case disposition on the job.[24]

We now present results using the estimated judges' fixed-effects obtained in the previous

[24]Table A3 shows that the results are robust to using the rankings on admission exams as explanatory variables instead of ranking quintiles. Since lower number rankings indicate better performance, the negative coefficients indicate that better ranked judges have higher output.

section. Figure 4 presents non-parametric evidence of the correlation between (residualized) ranks in admission exams and standardized FE.[25] The strong positive correlation between performance measures suggests that judges who perform well in the admission exams are also among the ones with highest FE in their cohorts.

In Table 7 we present this same evidence in regression form. We estimate simple OLS regressions at the judge-level, using measures of on-the-job performance (standardized fixed-effect) as dependent variables and quintiles of performance in the recruitment exam as the main explanatory variable. Column (1) presents results from an OLS regression including cohort fixed-effects. Consistent with the findings in the reduced form regression, our results suggest that being ranked in the top 20% in the admission exam is correlated with a 0.2 s.d. increase in judge's performance (estimated fixed-effects) in comparison to those in the bottom quintile. Those ranking in lower quintiles are also estimated to perform 0.1 - 0.15 s.d. higher when compared to those at the very bottom. In Column (2) we replace the quintile ranking in the admission exam with the standardized final grade used to construct ranking.[26] The coefficient on grade is significant and indicates that an increase of 1 standard deviation in final grade is correlated with a 0.07 s.d. increase in performance (measured by judges' fixed-effects). Taken together with the results from the reduced-form model, this suggests that, among the candidates selected in the admissions exam, those that rank higher do perform better on the job than those ranking lower.

While we believe documenting that the overall ranking is informative about job performance is an important result, it does not shed light on exactly which dimension of the screening process is leading to this positive correlation. It is possible, for example, that the Titles Exam, that takes into account previous work and academic accomplishments, is the most predictive component of the overall ranking. Or that the Oral Exam, in which there exists some degree of discretion by the selection committee, would be more informative. We attempt to provide evidence on that question by re-estimating the previous equation using grades in each exam phase as dependent variables and assessing which of those are more predictive about job performance.[27] As previously discussed, we restrict our analysis to 20 examinations and 619 judges for whom we observe six separate grades: Objective Exam, Written Exam, Civil and Criminal case decisions, Oral Exams and "Titles" Exam.

Results are reported in Columns (3) and (4) of Table 7. We first report in Column (3) the results of estimating the equivalent equation of Column (2) in the subsample for which we have detailed grade information. The result is very similar to that obtained in the full sample, suggesting that candidates with higher final grades also perform better on the job. We then

[25] Since we only compare judges entering in the same cohort, we first regress each rank on cohort indicators and use residuals to construct the binned scatterplot

[26] We could not collect final grades for some of the cohorts, therefore the smaller sample size in Column (2)

[27] In Table A2 we present pairwise correlations between grades in each of the admission exams phases. Correlations are often insignificant and not very large, suggesting that performing well in one particular phase of the admission process is generally not a good predictor of performance in other phases.

estimate the model including standardized grades in each of the exams separately, and report results in Column (4). The only coefficient that is significant, and also the largest in magnitude, is that of grades on the Judicial Decision Writing on civil cases (the coefficient on criminal cases is less than half the size in magnitude and not statistically different from zero). As shown below, this result is robust to other specifications of the estimation equation, suggesting that the civil case admission is indeed the most predictive component of the admission exam.

Recall that, since the harmonization of admission exams in 2009, each of the Judicial Decision Writing exams has weight 15% for the final ranking, so grades in the civil case decision contribute less to the final selection than grades in the written exam (30% weight) or Oral exam (20%). Our results suggest, in contrast, that if the goal is to select candidates who will increase the speed of case disposition, exams should overweight results in the civil case decision.

5.4 Results are robust to alternative specifications

We conduct several exercises to assess the robustness of our results. First, Table 8 presents regressions in which we drop top and bottom performers in each cohort, evaluating whether results are fully driven by the very best (or very worst) candidates. Column (1) reproduces our main specification, while the remaining columns restrict the sample by dropping only the top 3 performers in each cohort (Column 2); the top 5% candidates in each cohort (Column 3); the bottom 5% candidates in each cohort (Column 4); and both the top and bottom 5% candidates in each cohort (Column 5). Estimates of the correlation between exam rank and FE are very stable, and we cannot reject they are statistically indistinguishable from our main specification.

In Table 9 we re-estimate the results of our main specification but use the rank of judges' FE as dependent variable instead of the standardized FE. Column (1) presents the coefficients on admission exam quintiles: among judges entering in the same cohort, those in the top quintile rank, on average, four positions higher than those in the bottom 20% (coefficients are negative since a better rank equals a lower rank number). Those in the second quintile rank 2.6 positions higher, on average, and those in the third and fourth quintile between 1.3-2 positions. Overall, the results confirm our main specification findings that candidates ranking better in the admission exam also perform better on the job. Column (2) uses the final grade as explanatory variable, showing that a unit s.d. increase in final grade is correlated with a 1.5 higher position in FE ranking. When we restrict the sample to those observations with detailed grades, in column (3), the coefficient on Final Grade is very similar in magnitude to that on the full sample. Finally, when we include separate grades by phases as predictors of judge FE we again find that the largest coefficient in magnitude and significant is that associated with civil case exam: an increase in 1 s.d. in the civil case grade is correlated with a 1.4 better ranking in performance.

We also perform a randomization inference exercise to assess the robustness of our find-

ings of the positive correlation between admission exam and job performance ranks. Within each cohort of judges, we randomly assign exam rankings, re-compute quintiles and then estimate the baseline model presented in column (1) of Table 7. Figure 9 presents the histogram of these 1,000 simulated beta-coefficients for the top 20% performance indicator, and the solid line marks the true coefficient of 0.227. 95% of estimated coefficients are on the interval [-.118, 0.118], and none of the estimates is larger in magnitude than the true estimate. These results suggest that it is very unlikely that we would obtain a coefficient of this magnitude purely by chance.

6 Conclusion

This paper provides evidence that states can effectively design impersonal exams that are able to screen good candidates for top public service positions, even when recruitment practices are constrained by fears of political influence. We explore rich data on judges and courts in Brazil to show that judges are relevant in explaining the observed variation in output, and estimate judge-level measures of performance in case disposition - an important indicator in a judicial system with high levels of court congestion. We then link these measures to judges' performance in the admission exams, and show that within cohorts of hired judges those with higher grades also dispose of more cases. In particular, it seems that not all phases of the admission exams are equally likely to predict job performance: across different specifications, grades on the civil case exam is the only statistically significant predictor.

Our results have meaningful implications for policy makers. First, it adds to recent evidence that not only frontline providers matter for the delivery of public service: managers and other officials working across the state bureaucracy can have significant impact on service provision (Best et al., 2017; Fenizia, 2019; Aman-Rana, 2020). Carefully designing systems that select and incentivize these individuals is therefore very important. Secondly, it is also relevant for the debate about rules and discretion in hiring (Hoffman et al., 2018). We show that an admission process with little discretion by the selecting agency is able to rank individuals in a way that meaningfully predicts job performance. In particular, by breaking down exam performance in its component, we find evidence that an examination that approximates the kind of task faced by candidates on the job (the writing of sentences by judges) is especially predictive about their future performance.

Data limitations do not allow us to further explore two mechanisms we believe are relevant for future research. The first is what makes for an efficient judge. Judges do not work in isolation writing decisions, but, rather, manage complex organizations staffed by several workers and in close contact with other state actors (Pinheiro, 2003; Oliveira Gomes, 2014). A more efficient judge might be one that simply puts longer hours and more effort to increase case disposition, but might just as well be one that is able to put in place an well-oiled machine

where every staffer is pulling their weight and ensuring smooth handling of cases[28]. Management practices have shown to be very relevant in explaining productivity in both the private (Bloom & Van Reenen, 2007; Bloom et al., 2013) and the public sector (Rasul & Rogger, 2018; Leaver et al., 2019; Bloom et al., 2015), so gaining better understanding of working practices in the judicial sector might shed light on the determinants of judge effectiveness.

Second, while we found a strong and robust positive correlation between grades in the admission test and performance, and consider this is relevant parameter for policy-makers designing screening processes, it is unclear exactly what is the force driving this correlation. One possibility is that exams are indeed effective in screening candidates with specific knowledge that is also useful for the tasks performed by a judge - the fact that grades in the civil case examination are the only ones with independent predictive power suggest this might be the case. Another possibility, however, is that competitiveness and difficulty of the exams screen candidates with high general ability and/or high motivation to be a judge, which implies that the congruence between test content and requirements of the job is less important. We think this is an relevant distinction, particularly in light of the theory and evidence that highlight the role of intrinsic motivation in driving performance when high-powered incentives are limited (Deserranno, 2019; Ashraf & Bandiera, 2018; Prendergast, 2008).

[28] Fenizia (2019) finds that the mechanism through which managers in social security offices are able to increase output per worker is by letting go of workers while maintaining total output stable.

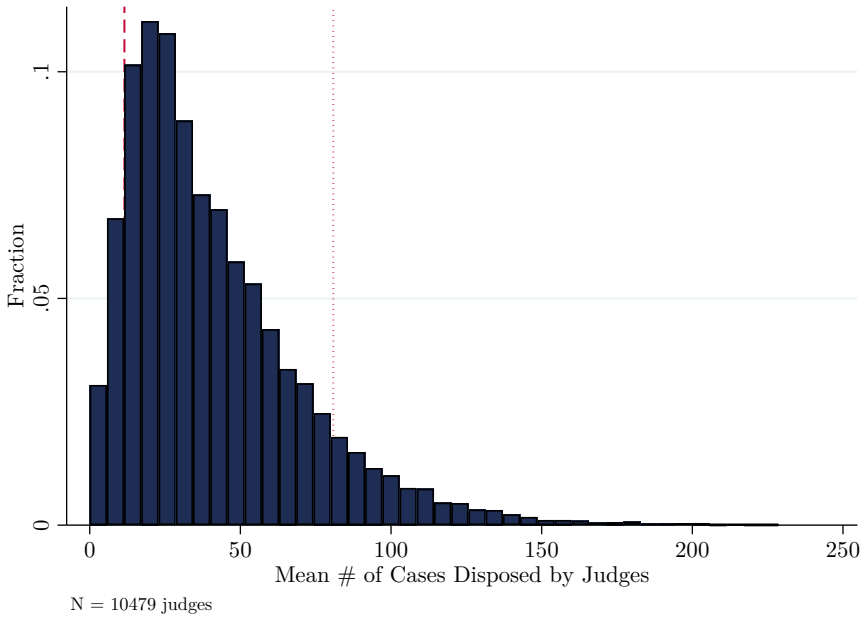
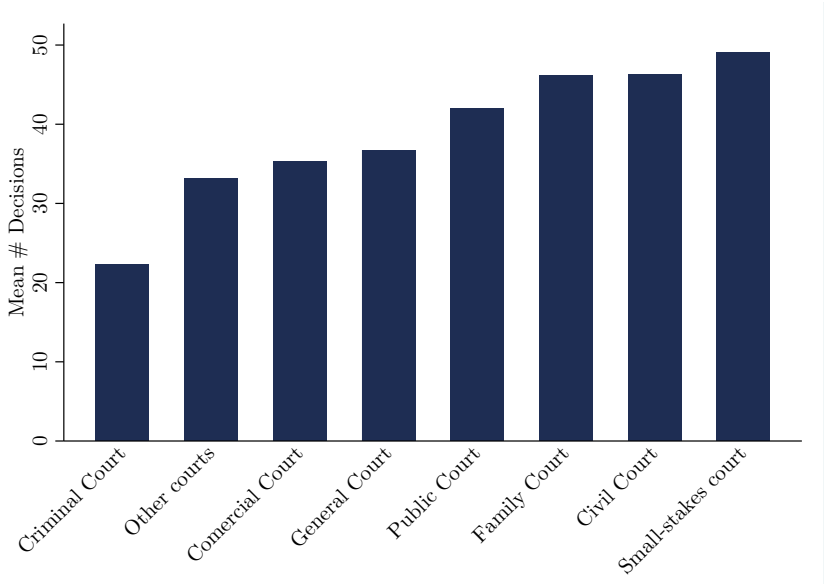
7 Figures and Tables

Figure 1: Histogram of mean number of cases disposed on the merits by judge.



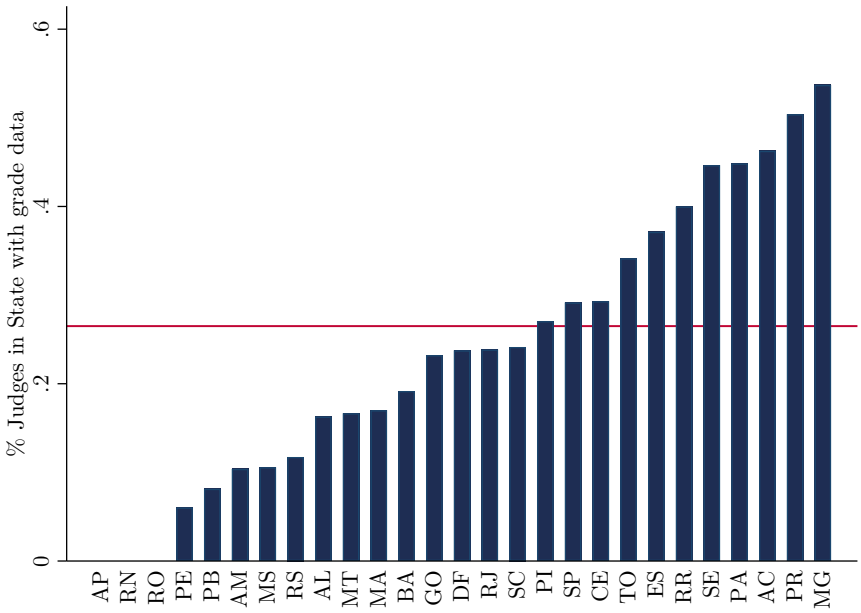
Note: The histogram presents the average monthly number of cases disposed by judges. Average number of cases is calculated in the sample used to estimate the two-way fixed-effects model, where outcome variables are trimmed at the top 1%, judge-court spells shorter than three months are dropped and only observations in the largest connected sets within each state are used. The dashed and dotted lines mark the 10th and 90th percentile of the distribution, respectively.

Figure 2: Average number of cases disposed, by type of court



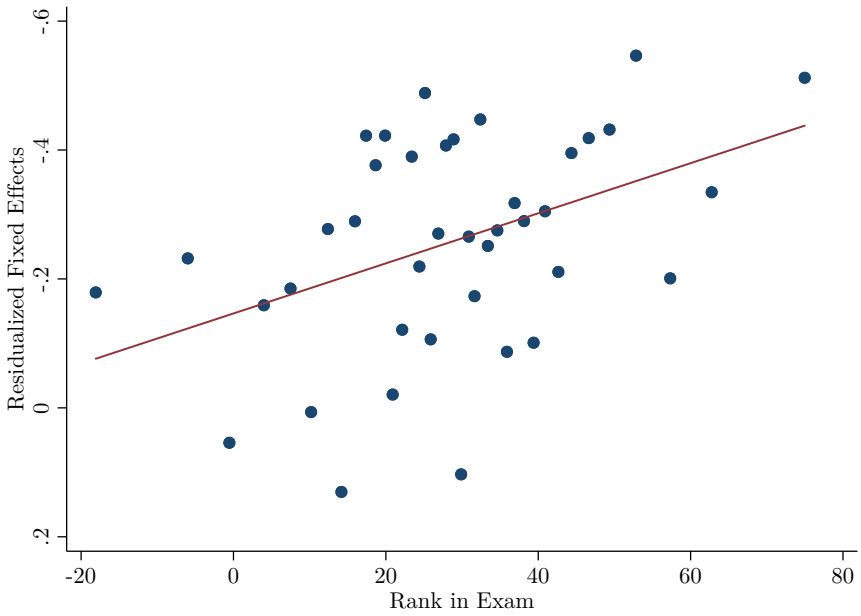
Note: The graph presents the average monthly number of cases disposed by judges, in each type of court. Number of cases is calculated in the sample used to estimate the two-way fixed-effects model, where outcome variables are trimmed at the top 1%, judge-court spells shorter than three months are dropped and only observations in the largest connected sets within each state are used.

Figure 3: Share of judges matched by State.



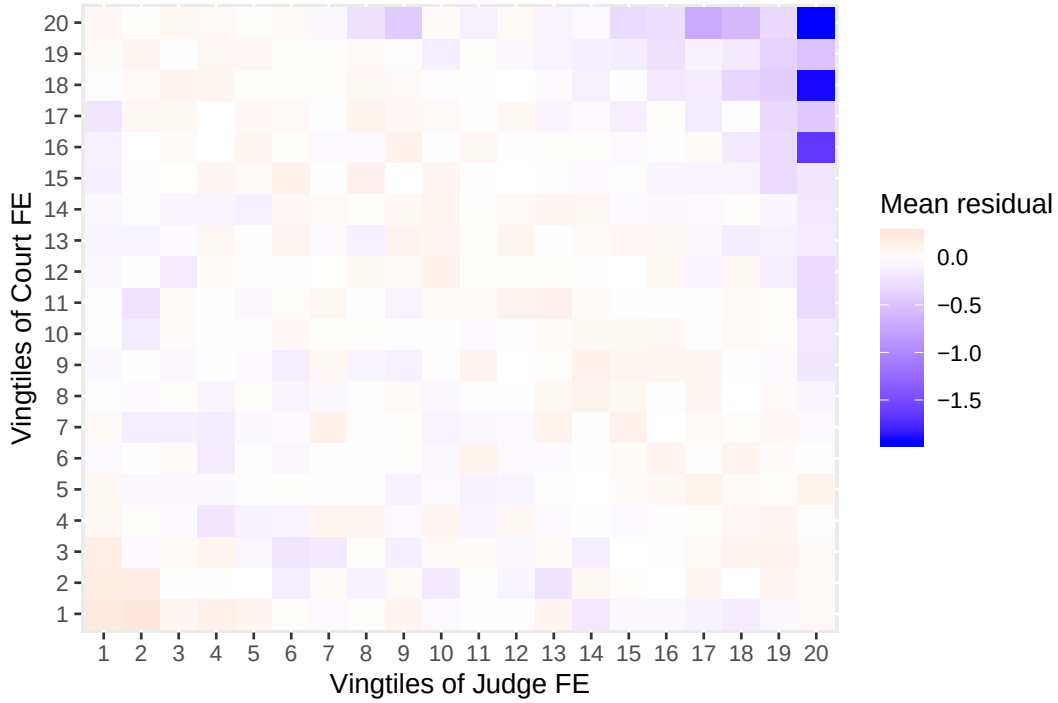
Note: The graph presents the share of judge in the estimation sample that are matched to admission exams, by State. The red line mark the overall share of judges matched (28%).

Figure 4: Binscatter of residual ranks, conditioning on Concurso FE



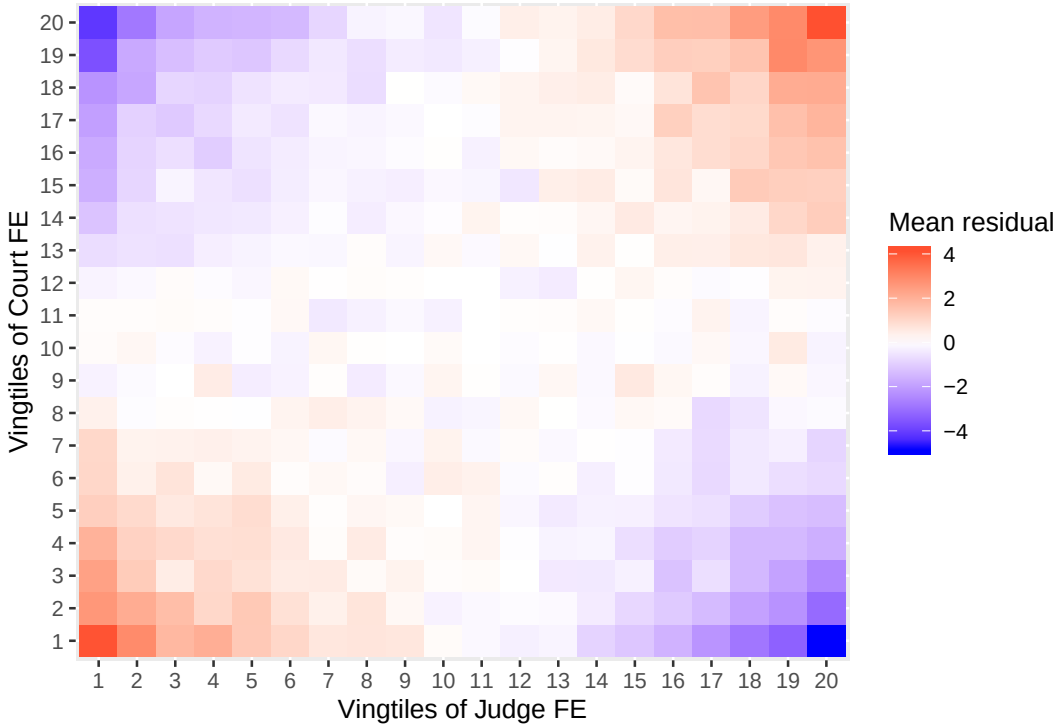
Note: The graph presents a binned scatter plot of residualized rank in fixed-effects obtained by estimating Equation (1) and residualized ranks in admission exams, at the judge level. Residues are obtained by regressing each of the variables on *Concurso* fixed effects.

Figure 5: Actual heatmap estimated from the data



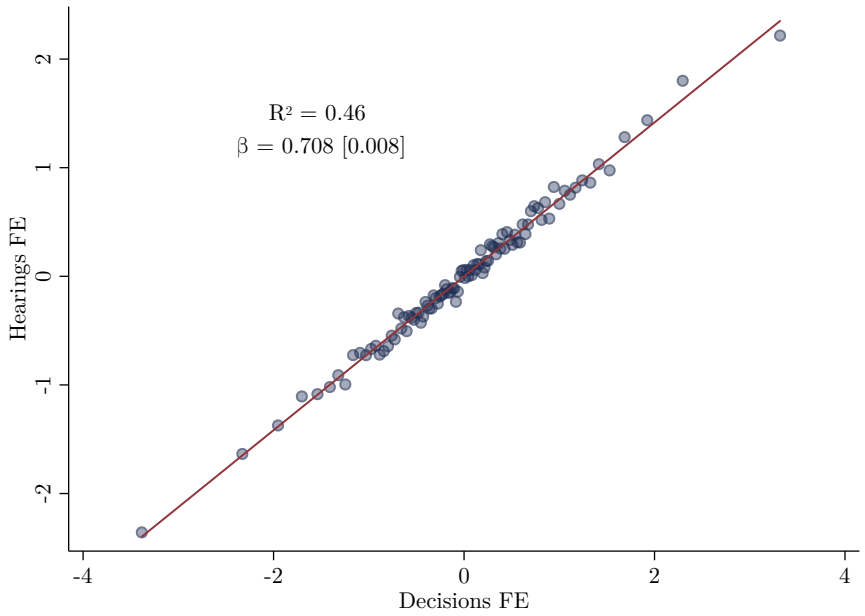
Note: This figure presents a heatmap of average residuals from the two-way fixed-effects model estimated from equation (1). Darker blue cells represent large negative residuals, while darker red cells represent large positive residuals. Judges and courts are binned into vingtiles of estimated fixed-effects.

Figure 6: Simulated residuals of misspecified model



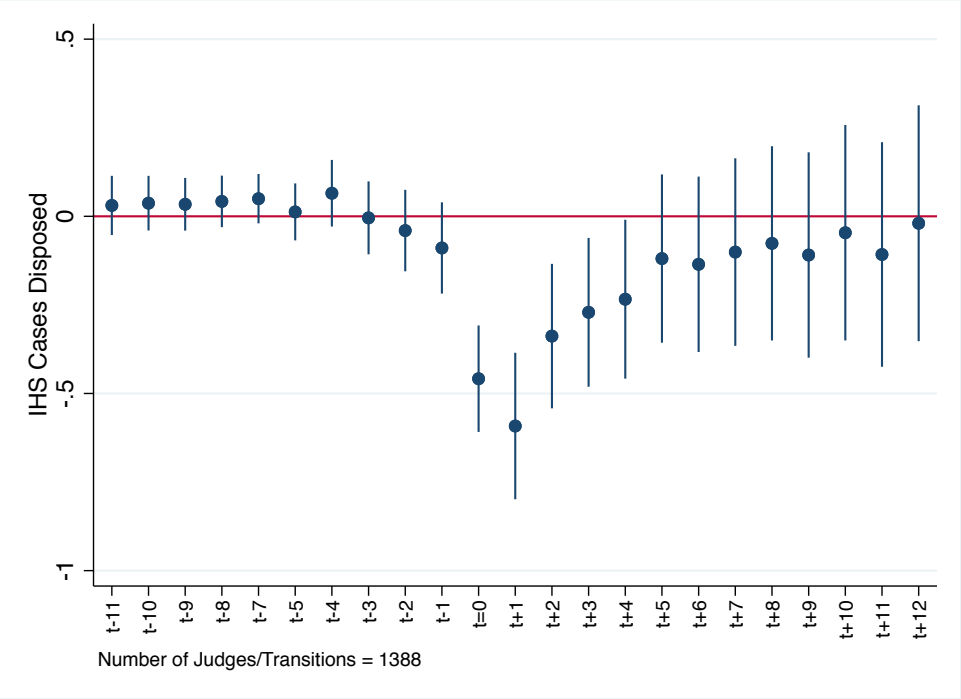
Note: This figure presents a heatmap of average residuals from estimating equation (1) using data from a simulated model that contains match effects between judge and courts.Darker blue cells represent large negative residuals, while darker red cells represent large positive residuals. Judges and courts are binned into vingtiles of estimated fixed-effects.

Figure 7: Binscatter of hearing and case disposition fixed-effects



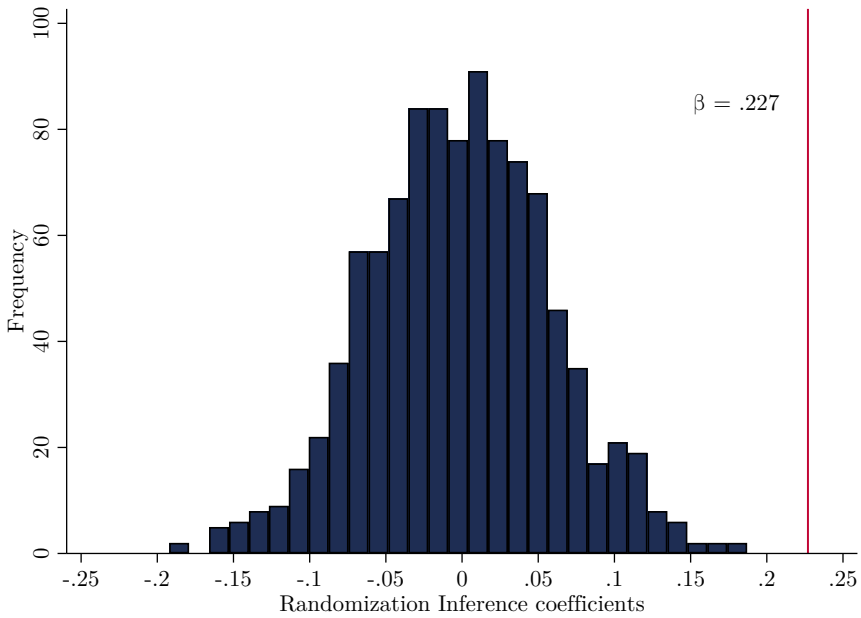
Note: This graph presents a binned scatter plot of residualized judge fixed-effects obtained by estimating equation (1) using hearings and case disposition separately. Residues are obtained by regression both FE on connected set dummies. The R-squared and coefficients presented refer to a regression of hearing FE on case disposition FE including connected set dummies.

Figure 8: Event-study around judicial district movement



Note: This figure reports point estimates and 95% CI for coefficients on an event-study regression, where the dependent variable is the IHS of cases disposed and the omitted category is the indicator for six months before the movement. Standard errors are clustered at the transition-level.

Figure 9: Histogram of simulated beta-coefficients



Note: The figure presents the histogram of 1,000 simulated coefficients for the top 20% indicator using our main specification, equivalent to the results presented in column (1) of Table 7, where we randomly assign final admissions ranking within each cohort. The true coefficient is marked by the solid red line

Table 1: Descriptive statistics

	Full Sample	Estimation Sample	Exam matched Sample
Judges			
Share male judges	0.61	0.60	0.61
Mean # courts by judge	10.52	4.28	5.87
Mean # months by judge	50.97	49.99	44.91
Mean # courts at judge-month level	1.70	1.39	1.55
Mean # judicial districts at judge-month level	3.72	2.28	3.29
Mean # months per judge-court pair	8.22	16.23	11.83
Courts			
Mean # of judges by court	12.64	4.96	2.99
Mean # judges at court-month level	1.67	1.38	1.20
Share civil courts	0.22	0.22	0.23
Share general courts	0.20	0.20	0.24
Share small-stakes courts	0.18	0.18	0.16
Share criminal courts	0.16	0.16	0.16
Share family court	0.10	0.10	0.09
Share other courts	0.14	0.13	0.11
Output measures			
Cases Disposed (on merit)	33.82	40.13	36.10
Total Hearings (presided or held)	29.32	34.88	35.85
Number of judges	11,462	10,479	2,881
Number judges ever working in multiple courts	10,378	8,500	2,653
Number of courts	9,540	9,048	5,667
Number of courts with multiple judges	9,201	8,152	3,925
Number of judge-court pairs	120,642	44,850	16,918
Number of judge-court spells	273,074	77,799	24,089
Number of connected sets	68	27	24
Number of judge-court-month observations	991,324	727,784	200,212

Note: This table reports descriptive statistics for key variables. Column (1) refers to the full original panel. Column (2) refers to the sample used to estimate the two-way fixed-effects model, where outcome variables are trimmed at the top 1%, judge-court spells shorter than three months are dropped and only observations in the largest connected sets within each state are used. Column (3) refers to the sample matched to admission exams, i.e., it only retains judge-court-month observations for which judges were matched to their admission exams ranking. This is the sample used in both the "reduced-form" exercises presented in Table **??** and the main results on the correlation between admission ranking and performance in Table 7.

Table 2: Goodness of fit measures

	(1)	(2)	(3)
R-squared	0.379	0.464	0.619
Adjusted R-squared	0.371	0.45	0.593
Residual Standard Error (RSE)	1.434	1.341	1.153
Observations	727784	727784	727784
Judge FE	No	Yes	No
Judge-by-Court FE	No	No	Yes

Note: This table presents goodness-of-fit measures for several different models using the two-way fixed-effects estimation sample. Column (1) presents results from a model that does not include judge fixed-effects; column (2) is our main specification from equation (1), including judge fixed-effects; while column (3) includes judge-by-court fixed effects.

Table 3: Variance decomposition

	Raw Variance	Split Sample Variance	Split sample Var - % Total
Cases disposed (IHS)	3.27	3.27	1.00
Judge FE	0.80	0.74	0.23
Court FE	1.16	1.10	0.34
Connected Set FE	0.24	0.22	0.07
Judge+Court FE	1.23	1.14	0.35

Note: This table presents the variance decomposition exercise using estimates from the two-way fixed effects model in equation (1). Column (1) presents the variance estimates without adjustment, while column (2) presents variance estimates corrected for finite-sample bias using the spit-sample technique. Column (3) presents the finite-sample corrected variance estimates as a share of total variance.

Table 4: Correlation between courts' fixed-effects and courts' characteristics

All grades are standardized to have unitary standard deviation within each admission cohort. Robust standard errors in parentheses (* p<0.1, ** p<0.05, *** p <0.01)

8 Appendix

A Appendix figures and tables

Table A1: Detailed descriptive statistics in estimation sample

	Mean	SD	Median	N
Panel A - Judges				
Male	0.60	0.49	1	10,218
# Courts by Judge	4.28	3.56	3	10,479
Number of months Judge is observed	49.99	21.05	56	10,479
# of Courts at Judge-Month level	1.39	0.83	1	523,813
Number Municipalities Judge ever works in	2.28	1.69	2	10,479
Unique number of months per judge-court pair	16.23	17.15	9	44,850
Panel B - Courts				
# Judges by Court	4.96	3.60	4	9,048
# of Judges at Court-Month level	1.38	0.87	1	528,483
Civil Court	0.22	0.42	0	9,048
General Court	0.20	0.40	0	9,048
Small-stakes Court	0.18	0.39	0	9,048
Criminal Court	0.16	0.37	0	9,048
Family Court	0.10	0.30	0	9,048
Other Courts	0.13	0.34	0	9,048
Panel C - Output measures				
Cases Disposed (on merit)	40.13	50.09	22	727,784
Total Hearings (presided or held)	34.88	46.39	17	716,736

Note: This table reports descriptive statistics for key variables in the sample used to estimate the two-way fixed-effects model, where outcome variables are trimmed at the top 1%, judge-court spells shorter than three months are dropped and only observations in the largest connected sets within each state are used.

Table A2: Pairwise correlations between performance in admission exam phases

	Objective	Written	Civil case	Criminal case	Oral	Titles
Objective	1					
Written	0.0283	1				
Civil case	0.0127	0.0144	1			
Criminal case	0.0276	0.0886**	0.0604	1		
Oral	0.0352	0.103**	0.112***	0.0656	1	
Titles	-0.0403	0.0825**	0.122***	0.0265	0.154***	1

Note: This table reports pairwise correlations between residualized grades in each one of the six phases of admission examinations. Residues are obtained by regressing grades on admission exam fixed-effects so all grades are represented as deviations from exam average. Sample is restricted to exams with available grades for all exams (N = 619).

Table A3: Regressions using admission ranking as explanatory variable

	(1)	(2)	(3)	(4)
Rank Exam	-0.00114	-0.00315***	-0.00305***	-0.00355***
	(0.000740)	(0.000581)	(0.000576)	(0.00124)
Observations	200,206	200,206	200,206	59,795
R-Squared	0.11	0.42	0.43	0.53
Concurso FE	Yes	Yes	Yes	Yes
Court FE	No	Yes	Yes	No
Month FE	No	No	Yes	No
Court-by-Month FE	No	No	No	Yes

Note: This table reports results from estimating equation (3): $y_{jcm} = \beta \text{ExamRank}_j + \gamma_c + \delta_{w(j)} + \boldsymbol{X}'_{jcm}\boldsymbol{\theta} + \epsilon_{jcm}$, where y_{jcm} is the inverse hyperbolic sine of cases disposed. All specifications include examination cohort (*Concurso*) fixed-effects. Columns (1) through (3) use the exam matched sample, observations used in the two-way fixed-effects models for which judge admission exams are available. Column (4) uses a subset of that sample that excludes all observations for which only one judge is working in any given court on a month. Standard-errors are clustered at the Judge level (* p < 0.1, ** p < 0.05, *** p < 0.01).

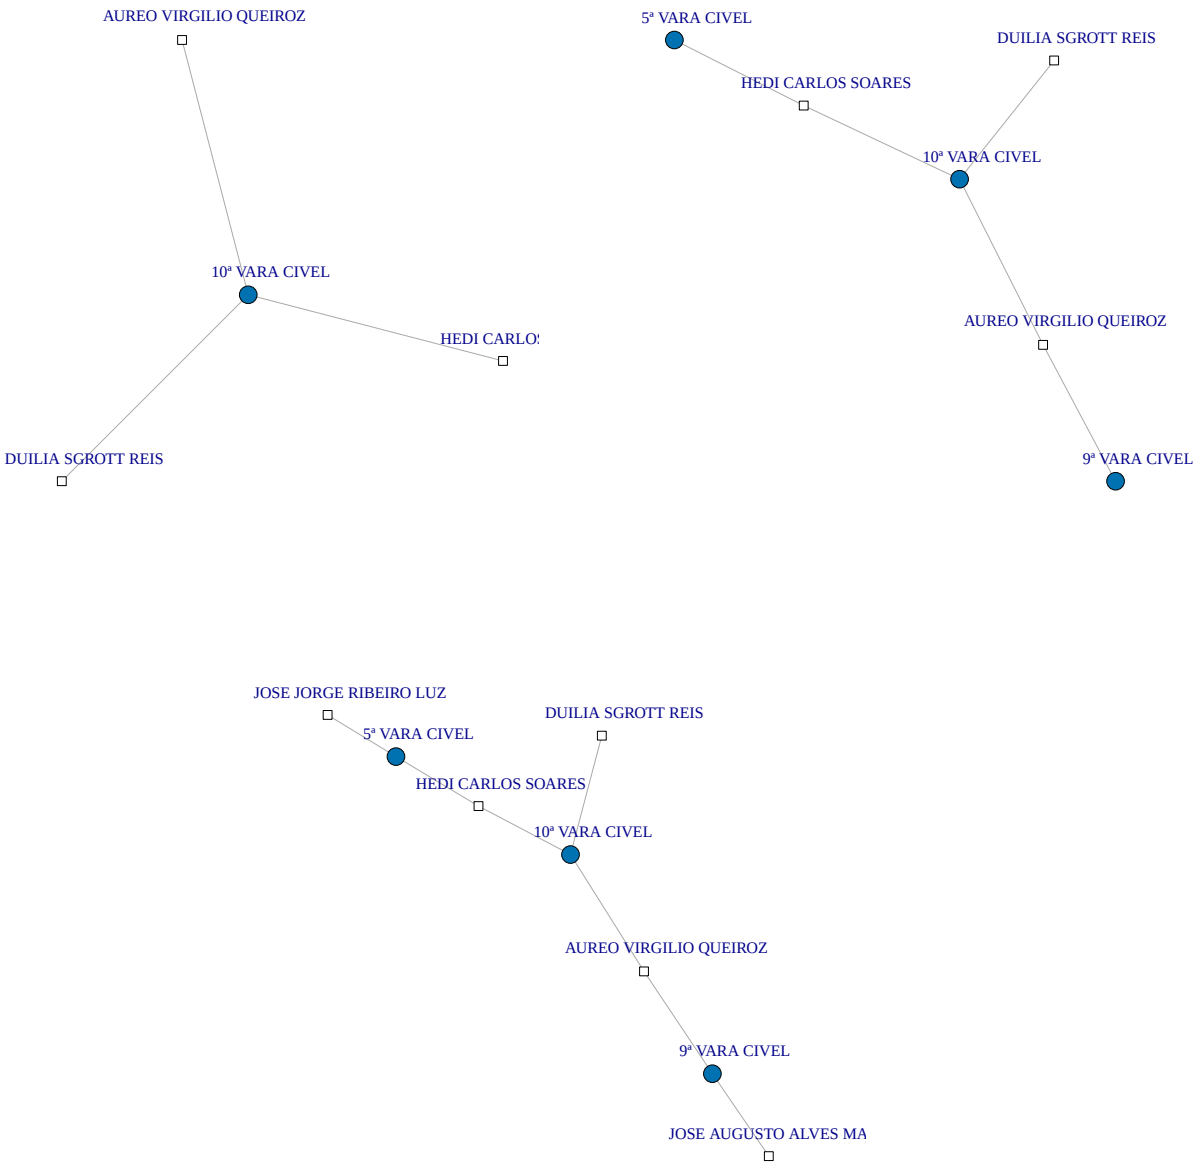
B Connected sets in the data

Connected sets are defined as as groups of organizations (courts) and individuals (judges) connected by "movers", workers who are observed in more than one organization. In our context, there are two sources of variation that allow us to construct connected sets. First, judges are often observed working in more than one court in the same month, allowing us to create connections even within a single period (month). Figure A1 below illustrates this fact. The top-right figure show three judges observed working in the 10th Civil Court of Porto Velho, in the state of Rondonia, during the month of May 2013. As we can see in the top-right figure, two of these judges also worked in additional courts in that same month - in the 5th Civil Court and the 9th Civil court. These two courts, and all the judges working in them on that same month, are also part of the original connected set - the bottom figure shows that two additional judges were working in these courts in May, and our connected set has expanded.

This within month connections is only one source of variation used to build connected sets. Since we have a panel that covers 76 months, we can build all connections that happened at any point in that period. Figure A2 takes a broader view of these connections and present all connections in the states of Rondonia and Amapa, two small states that allow for better visualization of the judge-court networks. The top two figures and the bottom-left one shows all connections for the states of Rondonia in three periods: 2009, 2009-2010 and 2009-2011. Note that when only connections in 2009 are considered, connected sets are large but multiple: clusters of judges and courts are often not connected to other parts of the network. When we explore judges' movements across several years, on the other hand, the network becomes more densely connected: if we consider the entire 2009-2015 period, all judges and courts *within each state* belong to a single connected set, as shown in bottom-right figure[29]. Since judges are hired to work in a specific state, nonetheless, the figure also shows that each state is a separate connected set: judges in the state of Rondonia, for example, are never observed matched to courts in Amapa, and vice-versa.

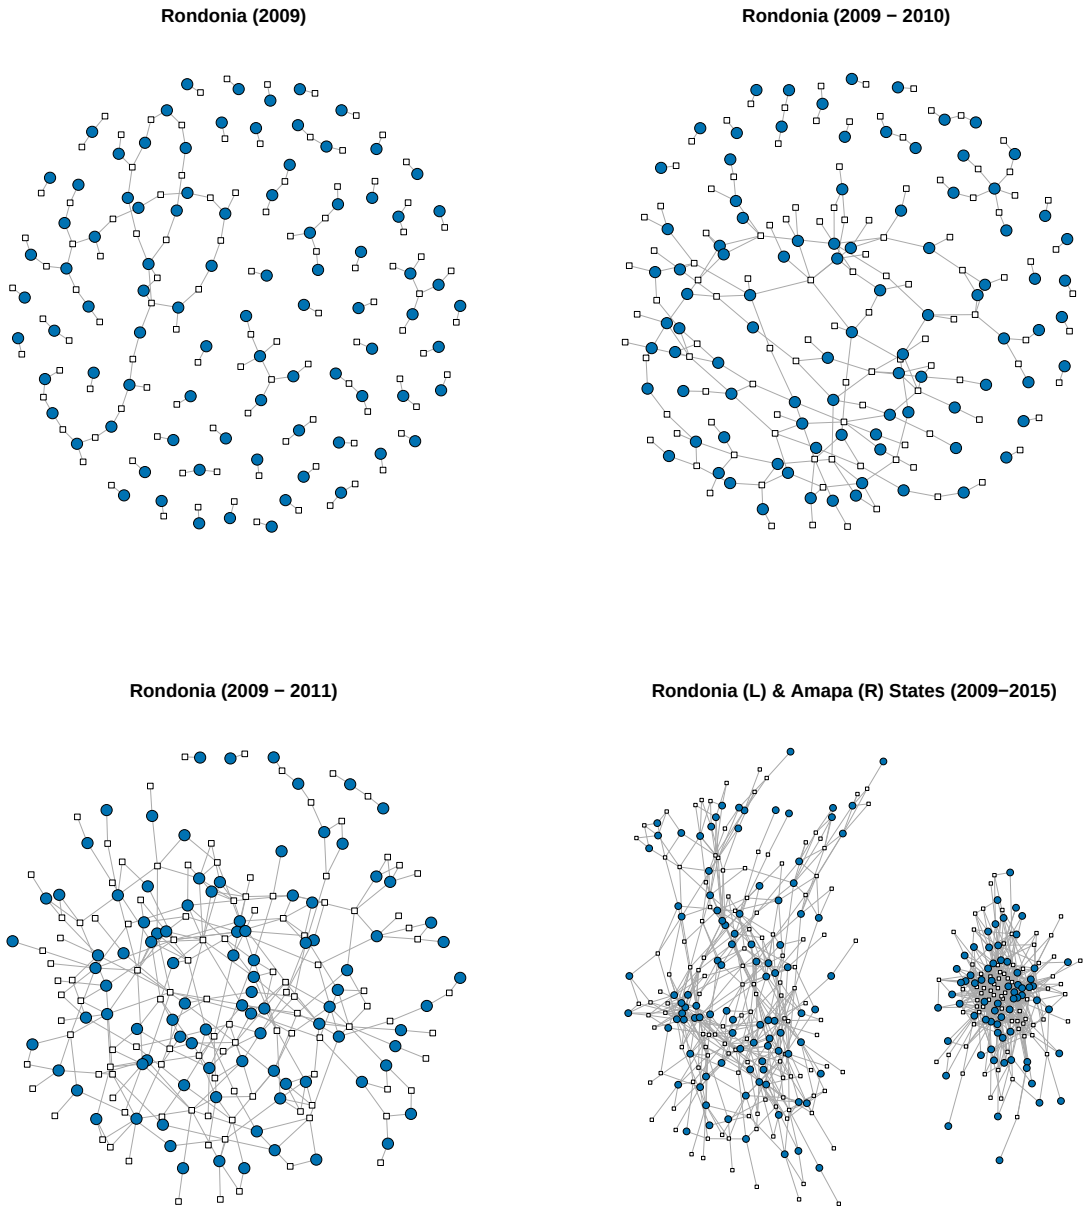
[29] All graphs represent connections in the sample used to estimate the two-way fixed-effects model, and therefore include a single connected-set by construction. As discussed above, nonetheless, the largest connected set within each state often includes over 95% of all observations.

Figure A1: Construction of connected sets in the data (Rondonia - May 2013)



Note: These graphs present the a selected network of judges (white squares) and courts (blue dots) in the state of Rondonia. Connections between dots and squares represent judges being observed working in a court in the month of May 2013. Starting from the top-left and moving clockwise, the graph expands the connected set by adding courts and judges observed paired in that month. All graphs use data from the sample used to estimate the two-way fixed-effects model.

Figure A2: Visualizing connected sets in the data



Note: These graphs present the networks of judges (white squares) and courts (blue dots) for the states of Rondonia and Amapa. Connections between dots and squares represent judges being observed working in a court in the referred period. The top-left figure presents connections observed in the state of Rondonia in 2009; the top-right includes connection observed in 2009 and 2010, while the bottom left presents connections in the period 2009-2011. The bottom right figure presents the universe of connections observed in in the entire panel for the states of Rondonia and Amapa. It highlights that there are no connection across states, since judges from one state are never observed working in a different state. All graphs use data from the sample used to estimate the two-way fixed-effects model, and therefore within each state all observations are connected by construction.
